

Step 1: Network Initialization

BA graph ($N = 1000$)
Seed pollution (10% / 30% / 50%)
Tag 1% super-spreaders

Step 2: Parameter Configuration

Select regime: None / Legal / Platform
Set legal (L , τL) or platform (α , np)

Step 3: Simulation Execution

Diffusion: polluted $\rightarrow$ neighbors
Governance: apply regime-specific action

Step 4: Effectiveness Calculation

Compute $E(t) = 1 - \frac{N_p(t)}{N}$ each tick
Average over 50 ticks $\times$ 10 replications

Step 5: Output Aggregation

Mean effectiveness per setting
